Case Study: CashKaro

Product: CashKaro, existing users

Reframe: Awareness problem to timing problem

Read: 5 minutes

Author: Godhuli Vyas

Checked, not present

CashKaro

Existing users still buy eligible purchases without going through CashKaro. The easy read is "awareness problem." After splitting the leak into its real parts and correcting an earlier draft's inflated math, it is **a timing problem with a much smaller, more honest fix.**

Deterministic rules | No AI in the loop | Evidence ranking | Bot contamination check

Key Insights:

A coupon in a drawer: users know it is there, but by checkout they have forgotten the drawer.

A missed purchase is one of three things, not two, and two of them look identical in the data.

The fix is the Recall Engine: one well-timed nudge, built on simple rules instead of AI.

Two different diseases

CashKaro

N

Never heard of CashKaro

Awareness

"I have never heard of CashKaro" is **an awareness problem** and belongs to marketing, not to this case study.

K

Knows it, forgot it

Timing

"I know CashKaro, I just did not think of it while buying." This is **a timing problem,** and it is what this case study is about.

A lost journey hides two populations

CashKaro

?

Stalled, still deciding

Clicked out and did not buy: distracted, comparing, or waiting for a sale. A memory problem. A well-timed nudge genuinely recovers this order.

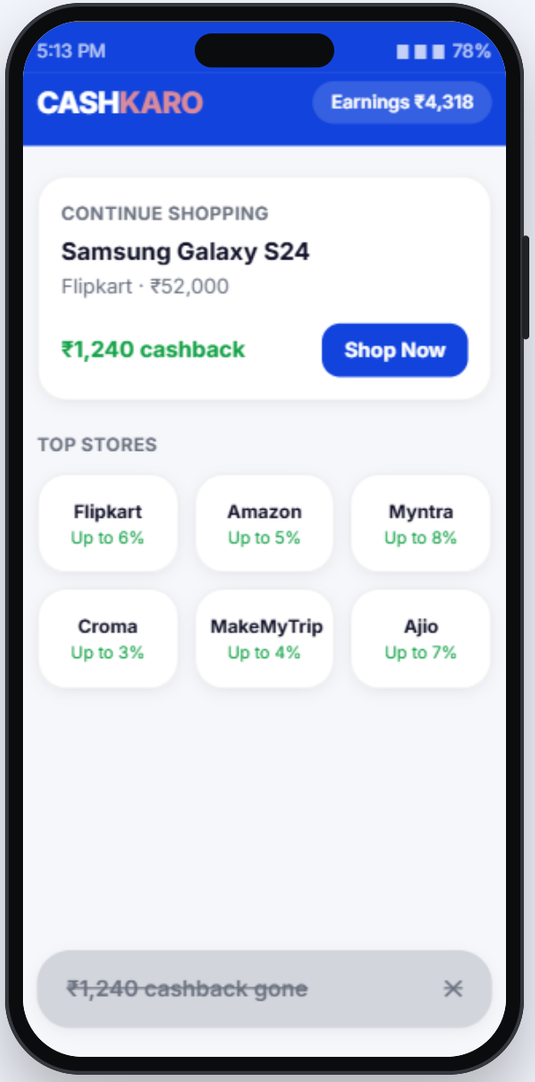

!

Bought, but tracking broke

A retailer app killed the cookie, an extension overwrote the code, an adblocker stripped parameters, or a later link took last-click. This user already paid.

The leak, on the real concept screen

CashKaro

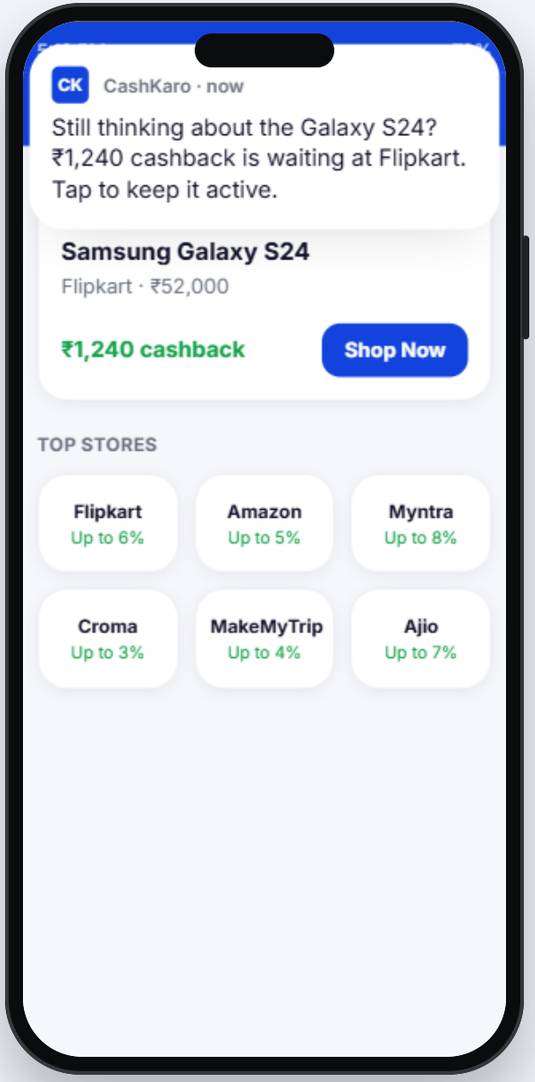

She clicks out to a retailer from **Continue shopping,** then goes quiet.

CashKaro sees the click-out, **but cannot see whether she is still deciding or already paid.**

The cashback is shown struck through as gone: the cost of forgetting at the moment of paying.

Solution: Never tell a paying customer her cashback failed.

The rule: wait, then nudge

The nudge fires only after a fixed minimum delay tied to **how long the retailer could take to report the order.**

The copy never asserts a negative: "Still thinking? Your cashback is waiting."

A separate message covers the already-paid case: "Your cashback may still be tracking, check here."

Solution: Proposed cap of two nudges a week, biased toward the largest stalled journey.

Recall Engine: three jobs, one nudge

CashKaro

1

Remind

Your cashback is waiting. Sent only after the retailer reporting window closes, then tuned by category.

2

Re-arm

The tap re-opens attribution, since some retailer windows only extend if the item is re-touched.

3

Defend

A creator link tapped while researching takes last-click. The re-tap puts CashKaro back in line before checkout.

Measurement: one number

CashKaro

NORTH STAR METRIC

Incremental tracked orders per existing user per quarter, nudged minus a held-out control

Nothing else counts as success on its own. This is a proposal, not a measured result.

LEADING INDICATORS

Nudge to tap, tap to click-out, click-out to tracked order.

GUARDRAILS

Push opt-outs and uninstalls, support tickets about nudges, and non-nudged orders inside the nudged group must not fall.

Rollout: safety first, then power

CashKaro

01
First cohort
Push only to users with a proven stalled click-out in a qualifying category.

→

02
Safety window
A short observation: opt-outs, complaints, mistimed nudges, the already-paid share.

→

03
Powered test
A held-out control for one full quarter.

→

04
Scale, iterate or kill
Decided against a pre-set bar on the North Star.

Where AI sits: nowhere in this loop, on purpose. Triggers, delays, caps and copy are deterministic rules, auditable when a nudge misfires. ML can come later for send time.

Who is actually reachable

CashKaro

Group	What we know	Treatment
Never arrived	No visit, no tag, no row.	Unreachable by the product. A marketing-budget question.
Visited, zero click-outs	Visible and reachable, never examined.	A nudge on exit or at the next session start.
Clicked out, no order	Reachable.	The Recall Engine, as specced.
Clicked out, order broke	Reachable, but already paid.	Attribution repair. Never "complete your purchase."

Bot check and order of work

CashKaro

01

Filter bots

Free, and it can kill the project: scrapers inflate click-outs and the opportunity.

→

02

Study the silent group

Visited, never clicked out: already visible and reachable.

→

03

Run Recall Engine

On the recoverable group, with a held-out control.

→

04

Size the invisible

Use a consented panel.

Recall Engine is still worth building. It moved from first in line to third, by arithmetic rather than preference.

Thank you for reading.
