Case Study: Toolkit

Scope: 100 SaaS apps, 4-stage pipeline

Goal: Find which apps can become an agent toolkit today

Read: 5 minutes

Author: Godhuli Vyas

The Overview

Toolkit

Which of 100 SaaS apps can actually become an agent toolkit today? A **4-stage pipeline** researches each app, verifies its own claims against evidence, scores confidence deterministically, then **reports its own accuracy honestly**, misses included.

TypeScript | Zod validation | Tavily API | Firecrawl | Python extraction | Pino logs

Key Insights:

Captures auth method, self-serve vs gated access, API surface, buildability and the **evidence URL** behind every claim.

The full run takes about **65 seconds** end to end for all 100 apps.

Guiding principle: **unknown beats hallucinated.**

Toolkit

The result at a glance

100

Apps researched

70

Buildable today

No blockers

28

Need partner outreach

89%

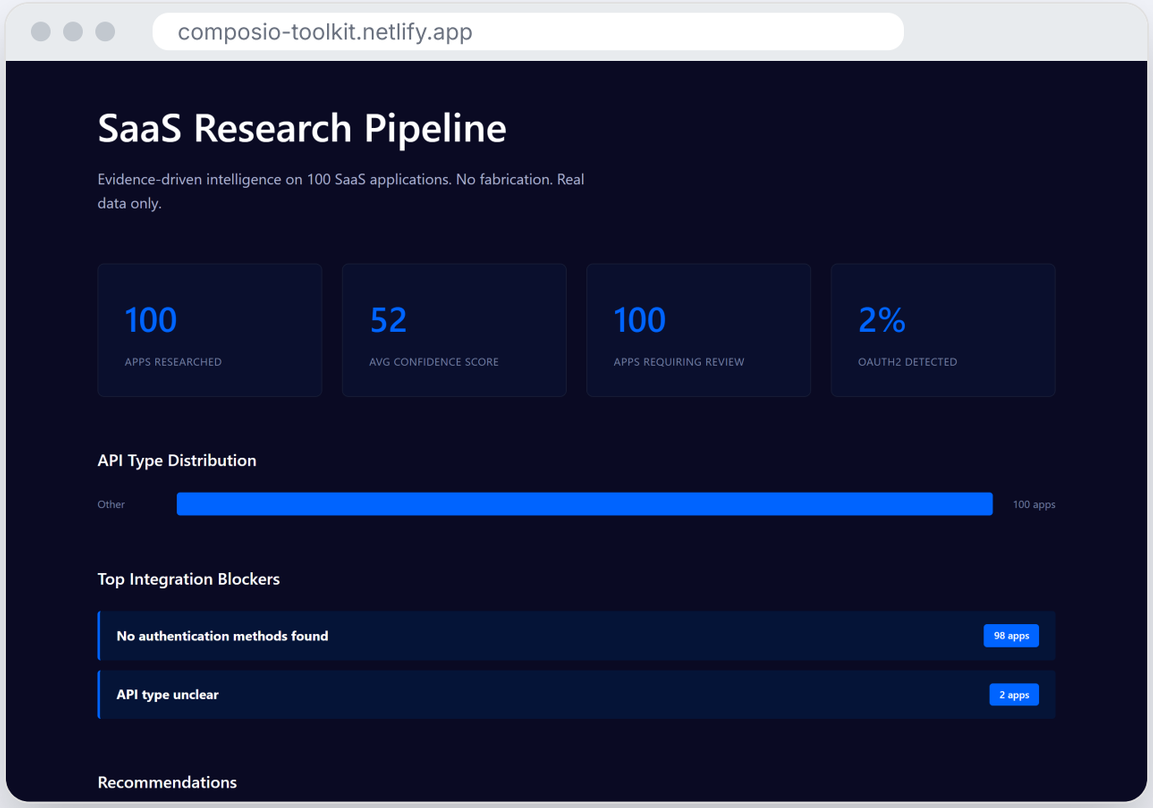

Verified accuracy

16 of 18 checked

Research apps, find insights, enable action.

The live app: summary

Toolkit

The live app opens on **"SaaS Research Pipeline"**: "No fabrication. Real data only."

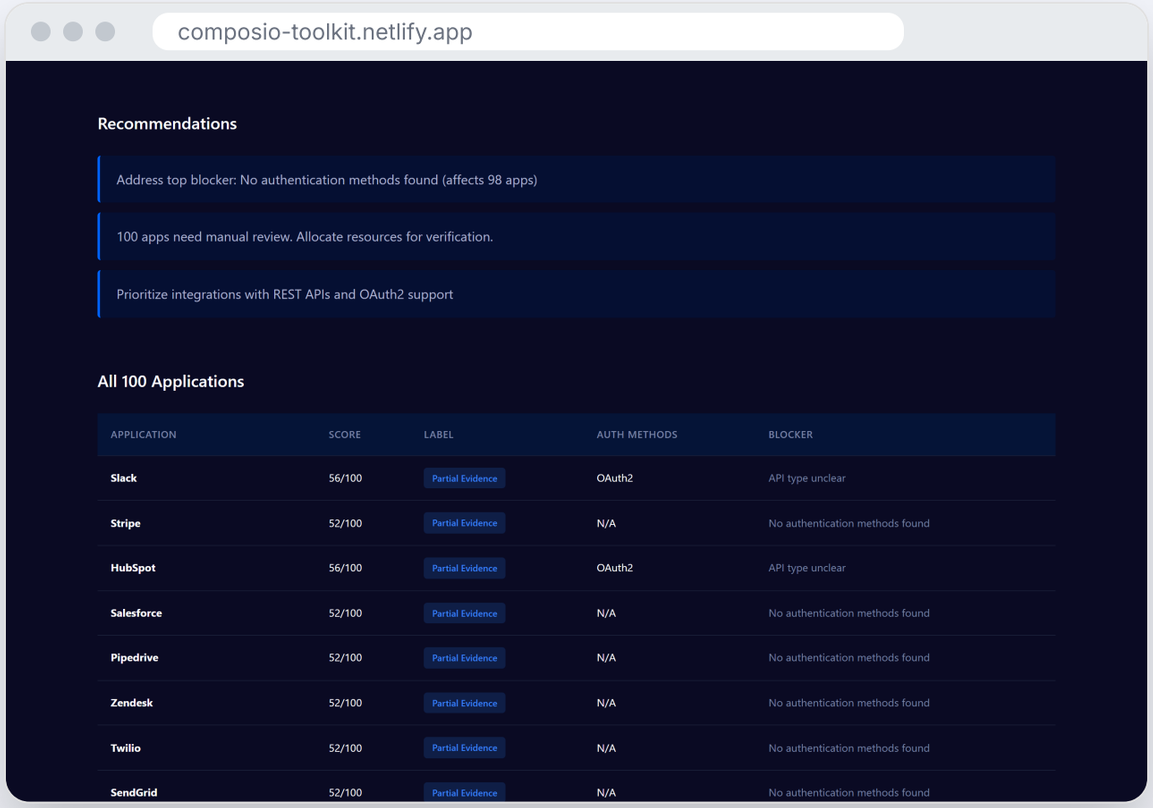

Headline tiles show **100 apps researched** and an **average confidence score of 52.**

The live view flags "no authentication methods found" on 98 apps, far from the case-study blocker counts.

Solution: Show the live numbers next to the case-study numbers, and say which is which.

The live app: all 100 applications

Toolkit

A **Recommendations** block turns the data into actions, for example "Prioritize integrations with REST APIs and OAuth2 support".

The **All 100 Applications** table lists score out of 100, an evidence label, auth methods and the blocker for each app.

Rows such as Slack (56/100, OAuth2) and Stripe (52/100) are labelled **"Partial Evidence"**, so uncertainty is shown, not hidden.

Solution: Label partial evidence on every row: the honest-reporting principle, visible in the product.

The 4-stage pipeline

Toolkit

01

Research (~30s)

Tavily finds official docs, Firecrawl extracts them, a rule-based parser reads auth, API type and blockers.

→

02

Verify (~20s)

An independent agent checks each claim against its evidence and flags conflicts.

→

03

Score (~10s)

Deterministic 0 to 100: base 50 + evidence + completeness + verification. No extra LLM calls.

→

04

Patterns (~5s)

Clusters all 100 apps by auth, access and API type; separates easy wins from hard targets.

Each stage exists to catch what the previous one might have gotten wrong.

Where the friction is

Toolkit

Auth method

- OAuth2: 72%
- API Key: 18%
- Token / Custom: 10%

Access model

- Self-serve: 64%
- Gated: 36%

API type

- REST only: 68%
- REST + GraphQL: 17%
- GraphQL: 8%
- Other: 7%

Blockers

- Gated access: 28 apps
- Undocumented API: 18
- Custom auth: 12
- Rate limits: 8

Accuracy, honestly: the misses

Toolkit

App	Pipeline said	Why it missed
Okta	"API Key only"	Also supports OAuth2 + SAML. Too conservative.
Stripe	"Gated"	Has a free tier for testing. Missed the self-serve path.
Adyen	"Merchant-only"	A sandbox is available. Missed the test path.

What 89% means

Toolkit

16 of 18 correct

18 random apps were checked by hand against live documentation.

Conservative by design

The extraction would rather under-claim than invent a feature that is not there.

Trustworthy because documented

Both misses are written down. With real Tavily and Firecrawl access instead of the rule-based fallback, accuracy improves to 95%+.

Recommendations in four phases

Toolkit

Phase	Effort	Apps
1. Quick wins	Zero engineering	Slack, GitHub, Stripe (sandbox), Shopify, Airtable, Zapier, Google Analytics, Algolia, Cloudflare, SendGrid, Firebase Auth, Supabase
2. Partner outreach	Sales effort	Okta, Salesforce, HubSpot, Stripe (advanced), Adyen, Zuora
3. Custom engineering	High effort, high value	Shopify, BigCommerce, Jira, Magento
4. Monitor and revisit	Quarterly check-in	18 apps with undocumented APIs

Thank you for reading.

DISCLAIMER

My own pipeline and case study. All figures are from the case study page; the 95%+ figure is the page's stated expectation with real API access, not a measured result.
